## Contents

1. **INTRODUCTION** .................................................. 8

1.1 **PIPES AND PIPE SYSTEMS** .................................. 9

1.1.1 General information ........................................ 9

1.1.2 Material ........................................................ 10

1.1.3 Nominal pressure ........................................... 10

1.1.4 Nominal width .............................................. 11

1.1.5 Temperature ................................................ 12

1.1.6 Flow processes ............................................ 12

1.2 **Pipe connections** .............................................. 15

1.2.1 General classification ...................................... 15

1.2.2 Detachable connections .................................... 16

1.2.3 Non-detachable connections ............................... 18

1.3 **Flange joint** ................................................... 19

1.3.1 Flange types ................................................ 19

1.3.2 Screws ........................................................ 21

1.3.3 Installation .................................................. 23

1.3.4 Tools .......................................................... 27

1.4 **Connecting elements for pipes** ............................ 28

1.4.1 Fittings ....................................................... 28

1.4.2 Screw pipes .................................................. 29

1.5 **Isometry of pipelines** ......................................... 30

1.5.1 Perspective and viewpoint ................................. 32

1.5.2 Isometric shading .......................................... 34

1.5.3 Dimensions, line weights, and graphical symbols in isometric drawings. 36

1.5.4 Troubleshooting in isometric drawings .................. 38

1.6 **Pipe systems** ................................................... 38

1.6.1 Linear expansion .......................................... 38

1.6.2 Pipe supports ............................................. 39

1.6.3 Graphical symbols ......................................... 40

1.6.4 Labeling in accordance with flow medium .............. 41

1.7 **Questions on the chapter “Pipes and pipe systems”** .......... 43

2. **FITTINGS** ......................................................... 44

2.1 **Introduction** ................................................... 44

2.2 **Classification of fitting based on construction** ............. 44

2.2.1 Requirements of fittings .................................. 45

2.2.2 External impermeability .................................... 46

2.2.3 Internal impermeability .................................... 47

2.2.4 Pressure losses in fittings .................................. 47

2.2.5 Properties of fittings (basic structures) .................... 48

2.3 **Structures of fittings** ......................................... 48

2.3.1 General classification ...................................... 48

2.3.2 Valves ........................................................ 49

2.3.3 Sliders ....................................................... 53

2.3.4 Cock .......................................................... 56

2.3.5 Flap ............................................................ 59

2.3.6 Diaphragm valve ........................................... 62

2.4 **Special fittings** ................................................ 64

2.4.1 Safety glass .................................................. 64

2.4.2 Dirt trap ...................................................... 64

2.4.3 Sampling valve ............................................. 65

2.5 **Faults with fittings** ............................................ 65

2.5.1 Generic ...................................................... 65
2.5.2 Causes of damage to fittings ................................................................. 65
2.5.3 Measures to minimize/avoid damage .................................................. 66

2.6 Graphic symbols .................................................................................. 67
2.6.1 Fittings ............................................................................................. 67
2.6.2 Actuators ......................................................................................... 68

2.7 Questions on the chapter “Fittings” ....................................................... 69

3 SAFETY FITTINGS .................................................................................. 70
3.1 Introduction .......................................................................................... 70

3.2 Safety valve .......................................................................................... 70
3.2.1 Classification based on construction ................................................... 70
3.2.2 Opening mechanism ........................................................................... 71
3.2.3 Installation hints ................................................................................ 72

3.3 Burst protection .................................................................................... 73
3.3.1 Classification based on construction ................................................... 73
3.3.2 Installation hints ................................................................................ 74

3.4 Steam trap ............................................................................................. 74
3.4.1 Classification based on construction ................................................... 75
3.4.2 Types of steam traps ........................................................................... 76
3.4.3 Installation hints ................................................................................ 78

3.5 Return flow preventers ......................................................................... 78
3.5.1 Classification based on construction ................................................... 78
3.5.2 Installation hints ................................................................................ 79

3.6 Bleeding and venting valves ................................................................. 80
3.6.1 Bleeding valve ................................................................................... 80
3.6.2 Venting valve ..................................................................................... 80

3.7 Anti-explosive devices ......................................................................... 81
3.7.1 Flame arresters .................................................................................. 82
3.7.2 Pressure release in a dust explosion ..................................................... 84

3.8 Questions on the chapter “Safety Fittings” ........................................... 84

4 STATIC AND DYNAMIC SEALS ............................................................. 85
4.1 General information on seals ................................................................. 85
4.1.1 Tasks of seals .................................................................................... 85
4.1.2 Classification of seals ......................................................................... 85
4.1.3 Waterproofing of static sealing surfaces ............................................ 85
4.1.4 Waterproofing of dynamic sealing surfaces ....................................... 87

4.2 Static seals ............................................................................................ 88
4.2.1 Flat seals ......................................................................................... 89
4.2.2 Profile seals ...................................................................................... 90
4.2.3 Welding ring seals ............................................................................. 91
4.2.4 Sealing compound ............................................................................ 92
4.2.5 Membrane and bellows ..................................................................... 92

4.3 Seals in flange connections .................................................................. 92
4.3.1 Shapes of sealing surfaces .................................................................. 92
4.3.2 Types of flange seal installation ......................................................... 93
4.3.3 Sealing face pressure ......................................................................... 94
4.3.4 Bolt force and torque ......................................................................... 96
4.3.5 Leaking flange connections ................................................................ 99

4.4 Dynamic seals on pumps ...................................................................... 100
4.4.1 Packing seal (packing gland) ............................................................... 100
4.4.2 Slide ring seals .................................................................................. 102
4.4.3 Dynamic seals on piston pumps .......................................................... 108

4.5 Questions on the chapter “Static and dynamic seals” ......................... 109

5 GENERAL PRINCIPLES OF CONVEYOR TECHNOLOGY ....................... 110
5.1 Definitions ........................................................................................... 110
5.1.1 Force ............................................................................................... 110
5.1.2 Effort ................................................................. 110
5.1.3 Energy ............................................................. 110
5.2 Physical conveyance principles ................................................................. 111
5.3 Basic Conveyance Principle (Working Approach) ................................................................. 112
5.3.1 Centrifugal force principle ................................................................. 112
5.3.2 Displacement principle ................................................................. 112
5.3.3 Bernoulli principle ................................................................. 112
5.4 Conveyance of hard materials ................................................................. 112
5.4.1 Discontinuous conveying ................................................................. 113
5.4.2 Continuous conveying ................................................................. 113
5.4.3 Conveying with machines ................................................................. 113

Introduction

E-Learning for the chemical profession

Many topical areas in the field of pipe system technology can only partially be described in a way that stands out through conventional media elements such as photos, graphics and texts. Understanding the interaction of functional links or processes, amid the increasing complexity of the subject matter to be conveyed, requires considerable abstractive ability, and is thus ultimately a question of the imagination of the learner. However, since it is unrealistic to presume the latter ability in all cases, there is a demand for new concepts and didactic approaches, which expand the potential for knowledge transfer of a book via modern media and in so doing, can both create a deeper understanding and improve the sustainability of the learning process.

The current textbook—pipe system technology—is a component of such cross-media knowledge transfer. The subject matter is closely oriented to the vocational training regulations of typical professions in industry, such as chemical technician, pharmaceutical technician or production specialist, but also to the maintenance vocations in the chemical industry (industrial mechanic and plant mechanic) as well as certain laboratory professions. The concept impresses as a meaningful supplement to the subject matter with interactive learning media. These optional, interactive software modules support the learning process by overcoming the very “limit of comprehension”, which presupposes a far-reaching abstractive ability. Processes and devices used in everyday chemical operations and laboratory work are attractively set using animations or visualized in a manner to boost understanding.

The existing highly practical draft is part of the multimedia collection of learning content, which have been compiled as part of the project E-Learning for the chemical profession (ELCH). The scientific monitoring, which supported the project progression and the content creation, was used to ensure the quality of solutions with regard to media studies and ergonomics.

The ELCH project, financed with the support of the German Ministry of Education and Research and funds from the European Social Fund, represents a successful attempt to create a comprehensive learning scenario, which combines established means with appealing, digital learning media.

The authors of the ELCH consortium

1 Pipes and Pipe Systems

1.1 General information

Pipes are tubular components, which connect individual system components with each other. Their function consists of conveying and transferring away media. Pipes are divided into two main groups: production pipes and transport pipes. Production pipes are pipes, which are required within production facilities. The term transport pipe, meanwhile, refers to pipes which are deployed for the conveyance of media over long distance (pipelines).

Since the pipes within chemical plants tend to be sealed systems, these pipes are also known as pipe systems or pipe networks.

In the chemical production plant, pipes are subject to certain operational requirements, such as:

- the chemical influences of the conveyed medium
- the temperature of the conveyed medium
- the pressure of the conveyed medium
- the flow speed of the conveyed medium

![Figure 1-1 Pipes at Marl Chemical Park](image)

The operational requirements influence the choice of:

- material
- wall thickness
- pressure class (PN)
- nominal diameter (DN) of the required pipe

The design of a pipe, such as the wall thickness and material used, may be defined in a selection of pipe classes that is specific to the particular company. The EU pipe classes form the basis for this selection.
1.1.1 Material

The selection of the material (e.g. steel, stainless steel, copper, PVC, glass) for a pipe is in line with the following requirements:

- Static and dynamic stresses
  e.g. maximum operating pressure, alternating pressure load
  for example the following are suited:

<table>
<thead>
<tr>
<th>Material</th>
<th>Property</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>Stainless steel</td>
<td>High tensile strength</td>
<td>Product-conveying pipes in operation</td>
</tr>
</tbody>
</table>

- Mechanical stresses
  e.g. flow velocity, abrasion resistance
  for example the following are suited:

<table>
<thead>
<tr>
<th>Material</th>
<th>Property</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>Steel</td>
<td>Abrasion-proof surface</td>
<td>Pipe for liquids, which contain solid particles</td>
</tr>
</tbody>
</table>

- Corrosion resistance
  for example the following are suited:

<table>
<thead>
<tr>
<th>Material</th>
<th>Property</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>Glass</td>
<td>Resistant against concentrated acids</td>
<td>Reactor vessel</td>
</tr>
</tbody>
</table>

- Thermal conductivity
  for example the following are suited:

<table>
<thead>
<tr>
<th>Material</th>
<th>Property</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>Aluminum</td>
<td>Good thermal conductivity</td>
<td>Heat exchanger</td>
</tr>
</tbody>
</table>

- Electrical conductivity
  for example the following is not suitable:

<table>
<thead>
<tr>
<th>Material</th>
<th>Property</th>
<th>Application</th>
</tr>
</thead>
<tbody>
<tr>
<td>PVC</td>
<td>Static charge</td>
<td>No applications in areas at risk of explosion</td>
</tr>
</tbody>
</table>

1.1.2 Nominal pressure

The nominal pressure PN (Pressure Nominal) is the benchmark for a nominal pressure stage and indicates the maximum tolerable limit for the internal overpressure of the pipe system. The nominal pressure is specified without units, but the number in context refers to the unit of bar. The nominal pressure reading always assumes an operating temperature of 20 °C.
The nominal pressure stages have been determined with numbers that are vital for everyday operational duties. In accordance with DIN EN 1333, the definition and selection of the nominal pressure (PN) is described. The following nominal pressure stages can be selected:

- PN 2.5
- PN 6
- PN 10
- PN 16
- PN 25
- PN 40
- PN 63
- PN 100
- PN 160
- PN 250
- PN 320
- PN 400

1.1.3 Nominal width

Pipes have diameters ranging from a few millimeters up to several meters. Pipes made of steel can be divided into a further two groups:

- Pipes for general use and
- Precision pipes.

The pipes for general use are characterized by the nominal width (DN, Diameter Nominal). This is a variable and without unit. In pipe terminology, the variable is defined as a dimensionless whole number with the DN abbreviation. Each nominal width is assigned to a defined connection size. The nominal widths are graduated such that the conveying capacity of a pipe from one nominal width to the next increases by around 60–100%.

Table 1-1 Nominal widths and diameter

</tr>
</tbody>
</table>

Based on the wall thickness of the pipe, there is a corresponding reduction, starting from the external diameter of the specific nominal width of the pipe cross-section. For pipes in general use, there are various pipe fittings. For drinking water pipes, galvanized steel pipes with threaded connections are also used.

For precision pipes, the external pipe diameter is specified to the nearest millimeter, e.g. Ø6, Ø8, Ø10, Ø12, Ø14, Ø16 etc.. These pipes are also produced with varying wall thicknesses.
1.1.4 Temperature

The Temperature, at which the fluid flows through the pipe system, influences the strength of the material. This ultimately also affects the permissible operating overpressure, with which the system can be operated.

The operating temperature, for which the nominal pressure (PN) applies, is determined at 20 °C. If the temperature increases, the strength of the material is reduced and hence also the maximum permissible pressure load of the pipe. This link must be taken into account by the constructor of a pipe system.

In Figure 1-2, the dependence of the permissible operating overpressure on temperature is shown. Here, two materials are compared, which are often used for pipes. Material S235JR is a structural steel, and material number 1.4571 stands for a non-rusting chrome-nickel steel (X6CrNiMoTi17-12-2).

![Figure 1-2 Dependence of the permissible operating overpressures on temperature]

1.1.5 Flow processes

As regards flow processes in pipes, a distinction is made between two forms of flow:

- laminar flows and
- turbulent flows.

For laminar flows, the liquid particles move while equi-distant from the pipe walls in an axial direction. Laminar flows ensue when both the resistances as well as the flow velocities along the pipe are small.

![Figure 1-3 Laminar flow]

For turbulent flows, the liquid particles move at continually varying distances from the pipe walls in an axial direction. Such turbulent flow occurs with a greater flow velocity and is aided by any resistances in the pipe (rough wall, fittings such as shut-off devices, measurement devices etc.).

![Figure 1-4 Turbulent flow]
Speed
The speed at which a liquid or gas moves through a pipe is described as the flow velocity. It is low within a pipe system with large cross-sections and vice versa. The flow velocity is measured in m/s and is represented by \( v \).

\[
V_{elocity}, v = \frac{s}{t}
\]

where \( s \) = Distance (distance covered)

\( t \) = Time

Volume flow
Volume flow describes the volume, which flows through a pipe within a specific time period. The volume flow remains the same at any point within a pipe system. It is measured in unit volume per time period (L/s or m\(^3\)/h) and represented by the symbol \( \dot{V} \).

\[
Volume \ flow, \ \dot{V} = A \cdot v
\]

where \( A \) = Area of the pipe cross-section at the point in question

\( v \) = Flow velocity

Mass flow
The mass, which flows through a pipe within a specific time period, is described as mass flow. The mass flow remains the same at any point within a pipe system. It is measured in kg/s or t/h and is represented by the symbol \( \dot{m} \).

\[
Mass \ flow, \ \dot{m} = \dot{V} \cdot \rho
\]

where \( \rho \) = density of liquid

Continuity equation
Within the body sections of a pipe, the volume flow \( \dot{V} = A \cdot v \) remains constant. If the cross-section of a pipe changes, likewise the flow velocity \( v \) will vary.

\[
\dot{V}_1 = \dot{V}_2
\]

\[
A_1 \cdot v_1 = A_2 \cdot v_2
\]

\[
\frac{v_1}{v_2} = \frac{A_2}{A_1}
\]

Figure 1-5  Continuity equation
The flow velocities therefore vary in inverse proportion to the corresponding cross-sectional pipe area (A).

### Example Calculation of the flow velocity

In a pipe of nominal width DN 50, a medium flows with a speed of $v_1 = 1.56 \ [m/s]$. What does the flow velocity of the material become if the pipe narrows to DN 25?

- $v_1 = 1.56 \ [m/s]$  \hspace{1cm}  $d_1 = 54.5 \ [mm]$  \\
  \hspace{1.5cm} \text{(DN 50:} \ d = 60.3 \ [mm] \ - \ 2 \cdot 2.9 \ [mm] \ \text{wall thickness)}  \\
- $v_2 = ? \ [m/s]$  \hspace{1cm}  $d_2 = 27.9 \ [mm]$  \\
  \hspace{1.5cm} \text{(DN 25:} \ d = 33.7 \ [mm] \ - \ 2 \cdot 2.9 \ [mm] \ \text{wall thickness)}

The following applies:

$$V_1 = V_2 \quad \text{and} \quad A_1 \cdot v_1 = A_2 \cdot v_2$$

Which means:

$$A_1 \cdot v_1 = A_2 \cdot v_2 \quad \text{insert in formula}$$

$$\frac{d_1^2 \cdot \pi}{4} \cdot v_1 = \frac{d_2^2 \cdot \pi}{4} \cdot v_2 \quad \text{rearranging the equation} \ (v_2)$$

$$v_2 = \frac{d_1^2 \cdot v_1}{d_2^2}$$

After inserting the numerical values $v_1 = 1,56 \ [m/s]$; $d_1 = 54,5 \ [mm]$ and $d_2 = 27,9 \ [mm]$ it follows

$$v_2 = \frac{(54.5 \ [mm])^2 \cdot 1.56 \ [m \cdot s^{-1}]}{(27.9 \ [mm])^2}$$

$$v_2 = \frac{2,970 \ [mm^2] \cdot 1.56 \ [m \cdot s^{-1}]}{778 \ [mm^2]}$$

The result is $v_2 = 6.0 \ [m/s]$. The DN 25 pipe has a diameter only around half the size (around twice as small) as the DN 50 pipe. The flow velocity, however, increases around fourfold, because the cross-sectional area of the pipe has been reduced to approximately one quarter.

### 1.1.6 Pipe characteristic curve

The material flow in a pipe network is hampered by frictional processes. This can be seen in the form of pressure loss along a pipe. The degree of the pressure loss depends among other things on:

- the roughness of the pipe wall,
- the fittings, e.g. shut-off devices, safety devices, thermowell pipes,
- the viscosity and density of the pumped medium and
- the flow velocity or volume flow.

These “hindrances” to the material flow are expressed in the pipe characteristic curve (or system characteristic curve, Figure 1-6).
The pipes characteristic curve represents the link between pressure loss in the pipe and the volume flow.

Figure 1-6 allows the following conclusions:
- Pipe network 2 has a higher pressure loss than pipe network 1
- Pipe network 2 has a higher resistance than pipe network 1 (e.g. more valves, smaller diameter)

1.2 Pipe connections

To connect individual pipes to each other, various different types of connection are in use, in each case striving to ensure the maximum possible sealing performance.

However, not only are pipes connected to each other, but in the same way, the equipment used within pipe systems (e.g. fittings).

1.2.1 General classification

Pipe connections are divided into two different main groups: detachable and non-detachable connections.

<td>Detachable</td>
</tr>
</tbody>
</table>
### 1.2.2 Detachable connections

The sleeve connection is hardly ever used within chemical plants. It is predominantly used within sewer networks, e.g. made of plastic or concrete. Sleeve connections may only be exposed to low pressure (a few mbar overpressure).

Flange connections, as an additional form of detachable connections, are separately described in Chapter 1.3.

**Screw pipe**

The screw pipe consists of a union nut, a cutting ring or clamping rings and the connecting members. Watertightness is achieved by tightening of the union nut on the members, whereby the sealing element is the cutting ring or the clamping rings. These pipe connections are characterized by the fact that they can often be reused multiple times.

**Example Cutting ring connection**

When tightening the screw connection, the cutting ring penetrates the pipe to a small extent and de-forms it to a minor extent. The seal of the screw pipe is ensured by the necking and by the conical areas between the screw joint and cutting ring.

![Diagram of a cutting ring connection](image-url)
During the initial assembly, the pipe end is shifted up until the stop in the screw pipe and the union nut is tightened finger tight. Subsequently, an open end wrench is used to further tighten the union nut.

During the assembly of the screw pipe or the re-assembly thereof, the manufacturer's details concerning the speed during tightening of the union nut must be complied with. In addition, the pipe must not be subject to any damage in the area of the screw joint, since this could otherwise cause leakage.

Table 1-3 Cutting ring and clamping ring compared

</tr>
</tbody>
</table>

The pipe diameters (external—Ø in mm) for all screw joints are regulated in accordance with DIN 3851, in which the preferred pipe diameter is specified with Ø3, Ø4, Ø5, Ø6, Ø8, Ø10, Ø12, Ø14, Ø16, Ø20, Ø25, Ø30 and Ø38.

**Screw connection with seal in thread**

Pipes, which carry drinking water, service water or heating gas, often have so-called thread fittings connected. The thread at the end of the pipe and the thread fitting is a Whitworth pipe thread. The internal thread is cylindrical and depending on the design, the external thread may be cylindrical or conical. The dimensions of the Whitworth pipe thread are specified in inches.
1.2.3 Non-detachable connections

Welded connection
In the field of pipe connection technology, the use of welded connections is preferred since they are the most cost-effective option. These involve material-integrated bonds and guarantee absolutely no leakage. The thermal and mechanical stress of welded connections depends on the welding material, the welding method and the degree to which the preparations for the welding work proceed smoothly.

In industry, welded seams on pipes, which are used for the transport of hazardous materials, are subject to multiple tests (e.g. pressure tests, X-ray, leakage tests).

Adhesive joint (sleeve)
Adhesive joints in pipe systems are manufactured using PVC cement sockets or PVC pipe fittings and a suitable adhesive. Not all plastics can be bonded to the same extent and hence uniformly. The cause is the wide-ranging chemical composition of plastics and the resulting differences in deformation when exposed to mechanical strains.
If work is carried out with PVC pipes, it is advantageous to use an adhesive with a solvent. The solvent diffuses into the surface of the sealing point and thus facilitates the interaction between the adhesive and the parts to be connected together. This type of adhesive joint is comparable to the welding of plastics, but since it is carried out under cold conditions, it is referred to in terms of adhesives.

Press connection (sleeve)
The connection of pipes with the use of press connections is increasingly popular in areas of drinking water, rainwater, heating technology, compressed air and gas pipes. With the pressing tool (hydraulic pliers), the installation of the pipes can be performed swiftly and cleanly. The pipe connection is made without exposing the pipe material to any thermal stress. The key when using press connections, is to ensure that with consideration of the material to be conveyed, the correct choice of fitting and O ring seal is ensured. The pipe is inserted up to the stop point into the fitting (e.g. sleeve) and then pressed with the pressing tool. The pipe should not be exposed to any sharp outside burrs, since otherwise the O ring will be damaged.

Solder connection (sleeve)
When connecting pipes via soldering, this involves identical or differing metallic materials being bonded to each other. This method is mainly used for copper pipes and the scope of application is comparable to that of press connections. For the soldering process, a heat source is always required, to ensure the solder can be melted.

1.3 Flange joint
Flanges are governed by dimensional standards that are independent of the flange type. As a result, each standard applies to any flange with a particular nominal diameter and nominal pressure. All flanges have a bolt holes distributed evenly around the flange. The number of these holes is always a multiple of four.

1.3.1 Flange types
Different types of flange are used depending on the particular application, as listed in table 1-4.

Table 1-4 Flange joints

</tr>
<tr>
<td>Blank flange</td>
<td><img src="image3.png" alt="Diagram" /></td>
<td>A flange with no through-holes that closes up the pipe end</td>
</tr>
</tbody>
</table>
Flanges are also classified by the shape of their sealing faces. The different sealing face shapes are referred to by different code letters. The dimensions for the sealing faces are always based on the thickness of the flange face. The protrusions and recesses for tongue and groove sealing faces and the like are then designed accordingly.
